

Investor Package

BridgePoint Intelligence - product thesis, live execution evidence, moat, business model, milestones and diligence

September 7, 2026 - owner sprint snapshot

Data snapshot: 2026-09-08 03:00 UTC (live counters continue updating)

CONFIDENTIAL - INVESTOR DILIGENCE

Purpose of this document

A concise investor-ready diligence package that explains the BridgePoint thesis, current system evidence, technical moat, business model, milestone plan, use of capital and risks without presenting unverified projections as facts.

1. Investment snapshot

159.0M Canonical properties national property foundation	136.15M Addresses connected address estimate	13,999,751 Signals + patterns 12.59M signals + 1.41M patterns	11,093 Qualified opportunities strict opportunity layer
793 Registered sources public pulse source count	224.0M Source records connected source rows estimate	~51.2M Building geometries physical-world baseline	1,776 Claims sources covered across 56 tracked jurisdictions

Important diligence note: broad parcel identity coverage is much further along than exact rights-verified boundary geometry. Exact parcel boundaries are approximately 2.92M at this snapshot, or about 1.84% of canonical properties. BridgePoint reports those layers separately rather than presenting a single inflated completion number.

2. Problem

Property and claims intelligence is scattered across assessor systems, GIS services, permits, weather, fire/flood records, code systems, imagery, transaction records and local jurisdiction portals. A contractor, adjuster, investor or enterprise data team can spend significant time finding, normalizing and proving what belongs to one property. The data may be public, but the integration problem is not solved by a list of URLs.

3. Solution

- Normalize fragmented records into a canonical property identity with provenance.
- Continuously ingest lifecycle signals and attach them to the property timeline.
- Detect patterns and score evidence into explainable, role-specific opportunities.
- Add parcel/building/3D/imagery context so digital records are anchored to the physical asset.
- Expose source, recency, confidence and legal-use status instead of hiding uncertainty.
- Automate source health and failure recovery so the system can keep itself current.

4. Evidence of technical execution

- 159,006,975 canonical properties in the live system pulse.
- 100% state + D.C. jurisdiction representation in the current public jurisdiction metric.
- 136,150,151 address records estimated as connected nationwide.
- 12,585,725 signals plus 1,414,026 detected patterns at the latest pulse.
- 4,841,735 scored properties and 11,093 active qualified opportunities.
- Claims-lifecycle target model is already instantiated at 30 desired sources across 56 tracked jurisdiction codes; 1,776 source candidates are covered and 1,358 are currently healthy.
- Exact parcel boundary ingestion uses explicit rights, authority, provenance, privacy, local-law, allowed-use and freshness gates.
- National workers run under high-frequency cron, queue pressure and idempotent retry controls rather than manual one-off scripts.

5. Moat thesis

- Integration depth compounds: every new source adapter becomes reusable across properties, customers and future models.
- Canonical property identity and provenance make otherwise disconnected public records more useful together.
- A legal/use-governance ledger reduces the temptation to treat every accessible dataset as freely resellable.
- Operational tooling - sharding, health, source refresh, pressure gates and recovery - is difficult to recreate from a static data dump.
- Customer feedback can improve scoring, opportunity qualification and source prioritization over time, creating a product/data flywheel if retention proves strong.

6. Business model

Recurring SaaS packages currently range from \$99/month Starter to \$1,999/month All Intelligence, with Business at \$999, Enterprise at \$4,999+ and Custom Intelligence beginning at a \$499 minimum. The model can combine recurring access, higher-volume/company tiers, enterprise integration and custom intelligence.

The most important economic proof points are not theoretical market size: trial-to-paid conversion, retained customers, usage by workflow, cost to ingest/serve each geography, source licensing burden, gross margin and whether opportunities produce measurable customer value.

7. Use of capital - disciplined version

- Legal counsel and data licensing review for material commercial source agreements, enterprise contracts, privacy/terms and financing documents.
- Reliable infrastructure and storage for nationwide refresh, backups and customer demand, with cost telemetry rather than unlimited spend.
- Focused engineering/product support for data adapters, UI reliability, billing, team workflow and enterprise controls.
- Customer acquisition experiments tied to measurable conversion and retention rather than broad brand spend.
- Selective premium data partnerships where the paid source materially improves customer value and can be monetized with acceptable margin.

8. Near-term diligence milestones

- Complete remaining strict parcel denominator gaps and document canonicalization accuracy.
- Scale exact rights/provenance-verified parcel boundary coverage nationwide.
- Reach 25-30 healthy claims-lifecycle sources in every required jurisdiction, not only raw discovered candidates.
- Show property cards with correct address, source-linked timeline and reliable physical-world context.
- Convert signals/patterns into a higher count of truly qualified opportunities and measure customer outcomes.
- Produce reproducible export/backup, source/legal, technical, business and governance documentation.
- Establish first repeatable paid customer cohort and retention metrics.

9. Diligence questions an investor should ask

- How is a canonical property created, merged and prevented from duplicating?
- Which data sources permit commercial reuse, which are restricted, and how is that enforced?
- How much of the current parcel count includes exact geometry versus identity/address-only records?
- What is the error rate for property matches and stale addresses by state?
- What percentage of opportunities converts to customer action or revenue?

- What are normalized infrastructure/storage costs at current volume and projected customer usage?
- Which parts of the system are proprietary logic versus open/public data or licensed third-party material?
- What financing structure protects founder control while giving investors appropriate rights and information?

10. Risk statement

This package is an owner-prepared business/investor brief, not audited financial statements, a securities offering memorandum or legal advice. Counts are live system metrics and can change as canonicalization, dedupe, ingestion and provenance reconciliation continue. Any investment terms should be documented by qualified counsel.
